# Advances in Modeling Coal Pyrolysis, Char Combustion, and Soot Formation from Coal and Biomass Tar

**Thomas H. Fletcher**

Chemical Engineering Department

Brigham Young University

Provo, Utah, USA 84602

**Coauthors:**

David O. Lignell, Andrew Richards, Alex Josephson\*, Troy Holland\*

\*Currently at Los Alamos National Laboratory, Los Alamos, NM, USA

# Motivation:

## Improved Simulations of Coal Boilers

- We think we know a lot about
  - ✓ Coal pyrolysis
  - ✓ Char oxidation
  - ✓ Ash transformation & deposition
  - ✓ Soot formation
  - ✓ Radiative heat transfer
  - ✓  $\text{NO}_x$  and  $\text{SO}_x$  formation
  - ✓ Turbulence
  - ✓ Turbulence-chemistry interactions
- Do we really know all of this information?
- What else is there to know?

# Outline

1. Volatiles Composition
2. Soot formation
3. Char Oxidation

# Approaches to Gas-Phase Chemistry in Boiler Simulations

- Coal gas mixture fraction
  - 2 coal gas mixture fractions
- Eddy dissipation
  - Simple chemistry
  - Checks for mixing-limited reaction
- Assume pyrolysis gas species
  - Ignore turbulence?
  - Large eddy simulations?
  - Direct numerical simulations?
  - Combine with GRI-Mech or another large mechanism?

# Coal Gas Mixture Fraction

- Assumes all gases from coal have the same elemental composition
  - Char has same elemental composition as pyrolysis gases
- Local chemical equilibrium in gas phase
- Generally used with PDF based on turbulent mixing

- Smith, P. J.; Thomas H, F.; Smoot, L. D., Model for pulverized coal-fired reactors. Symposium (International) on Combustion 1981, 18, (1), 1285-1293.
- Brewster, B. S.; Baxter, L. L.; Smoot, L. D., Treatment of coal devolatilization in comprehensive combustion modeling. Energy & Fuels 1988, 2, (4), 362-370.
- Zhou, M.-m.; Parra-Álvarez, J. C.; Smith, P. J.; Isaac, B. J.; Thornock, J. N.; Wang, Y.; Smith, S. T., Large-eddy simulation of ash deposition in a large-scale laboratory furnace. Proceedings of the Combustion Institute 2019, 37, (4), 4409-4418.

# Two Coal Gas Mixture Fractions

- One mixture fraction for volatiles
- One mixture fraction for elements from char
- Each mixture fraction requires an elemental composition
  - Char assumed to be pure carbon
  - No distinction made for light gases vs. tar
- Local chemical equilibrium in gas phase
- Generally used with PDF based on turbulent mixing

# Species Assumed for Light Gas and Tar

- Light gas:

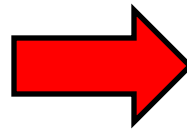

- $\text{CH}_4$

- Tar:

- Benzene ( $\text{C}_6\text{H}_6$ )

- Acetylene ( $\text{C}_2\text{H}_2$ )

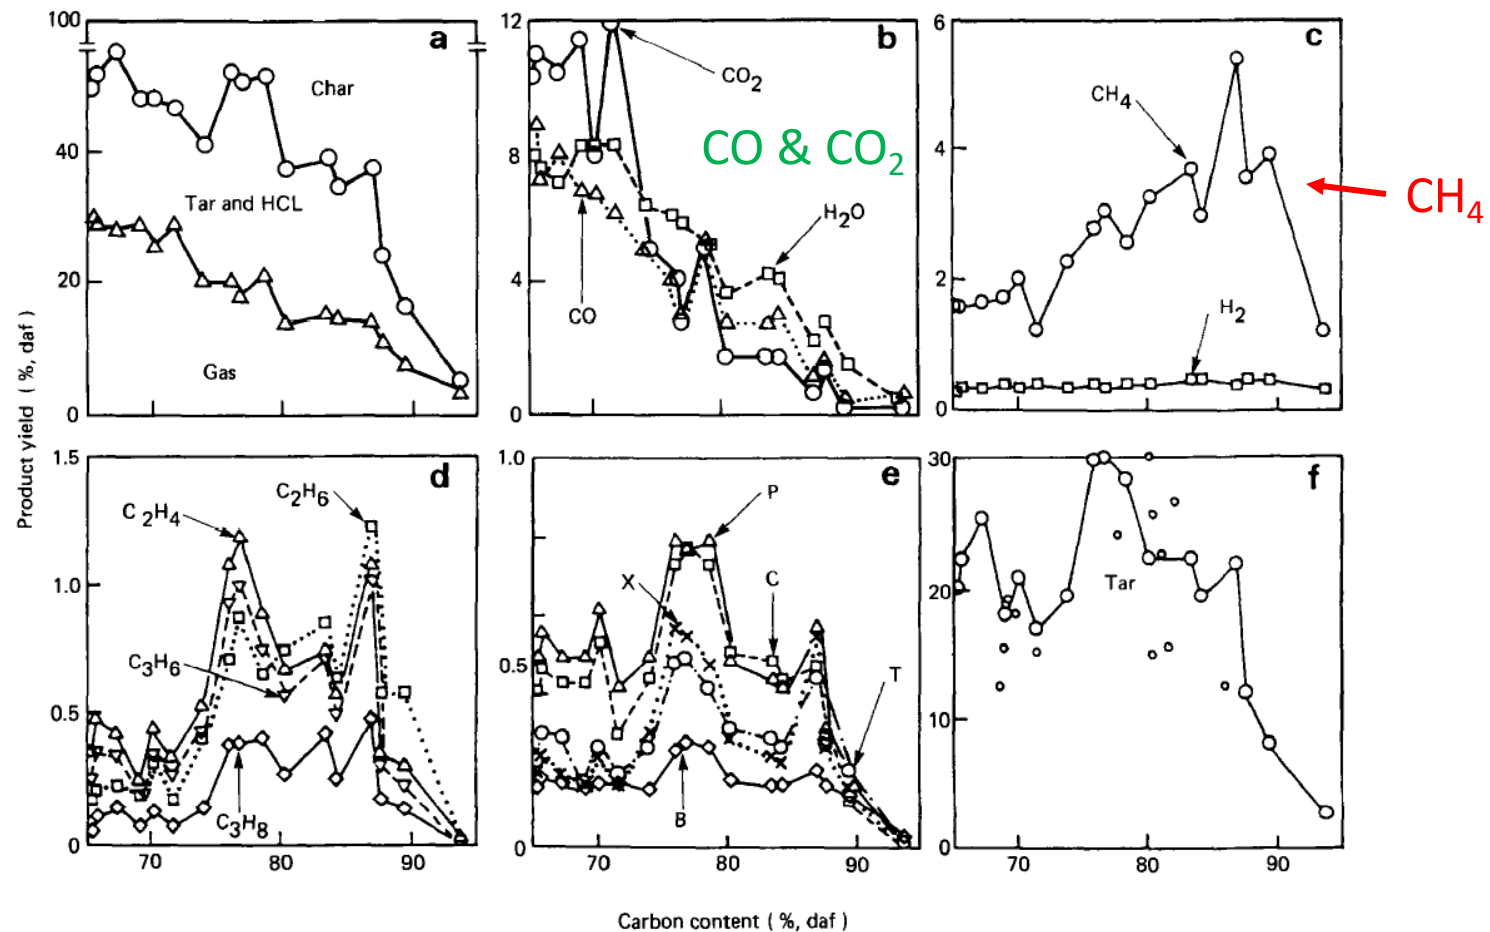

- Toluene ( $\text{C}_6\text{H}_5\text{CH}_3$ )

- Use detailed gas reaction mechanism, such as GRI-Mech
- Best used in laminar flow

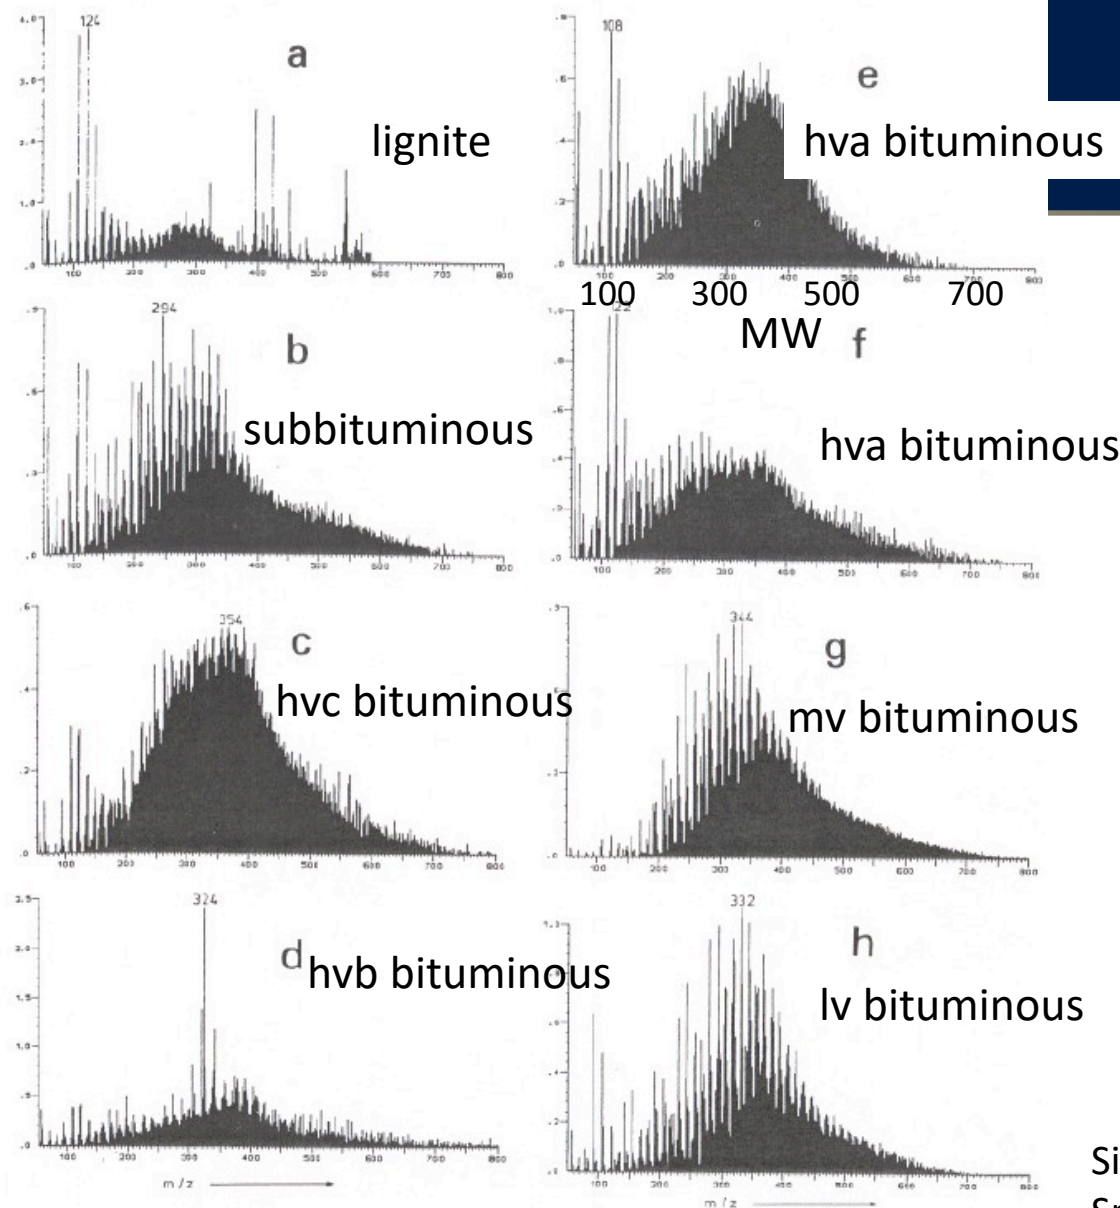

These are BAD assumptions

# Light Gas during Flash Pyrolysis (Xu & Tomita, Fuel, 1987)

**Figure 1** Effect of coal rank on yields of various products. (a) Gas including water, (tar + HCL) and char. (b) Oxygen-containing gases. (c) Methane and hydrogen. (d) C<sub>2</sub>-C<sub>3</sub> hydrocarbons. (e) Hydrocarbon liquids: B, benzene; T, toluene; X, xylene; P, phenol; C, cresol. (f) Tar: ○, Present values; ◻, Literature values

# Py-FIMS

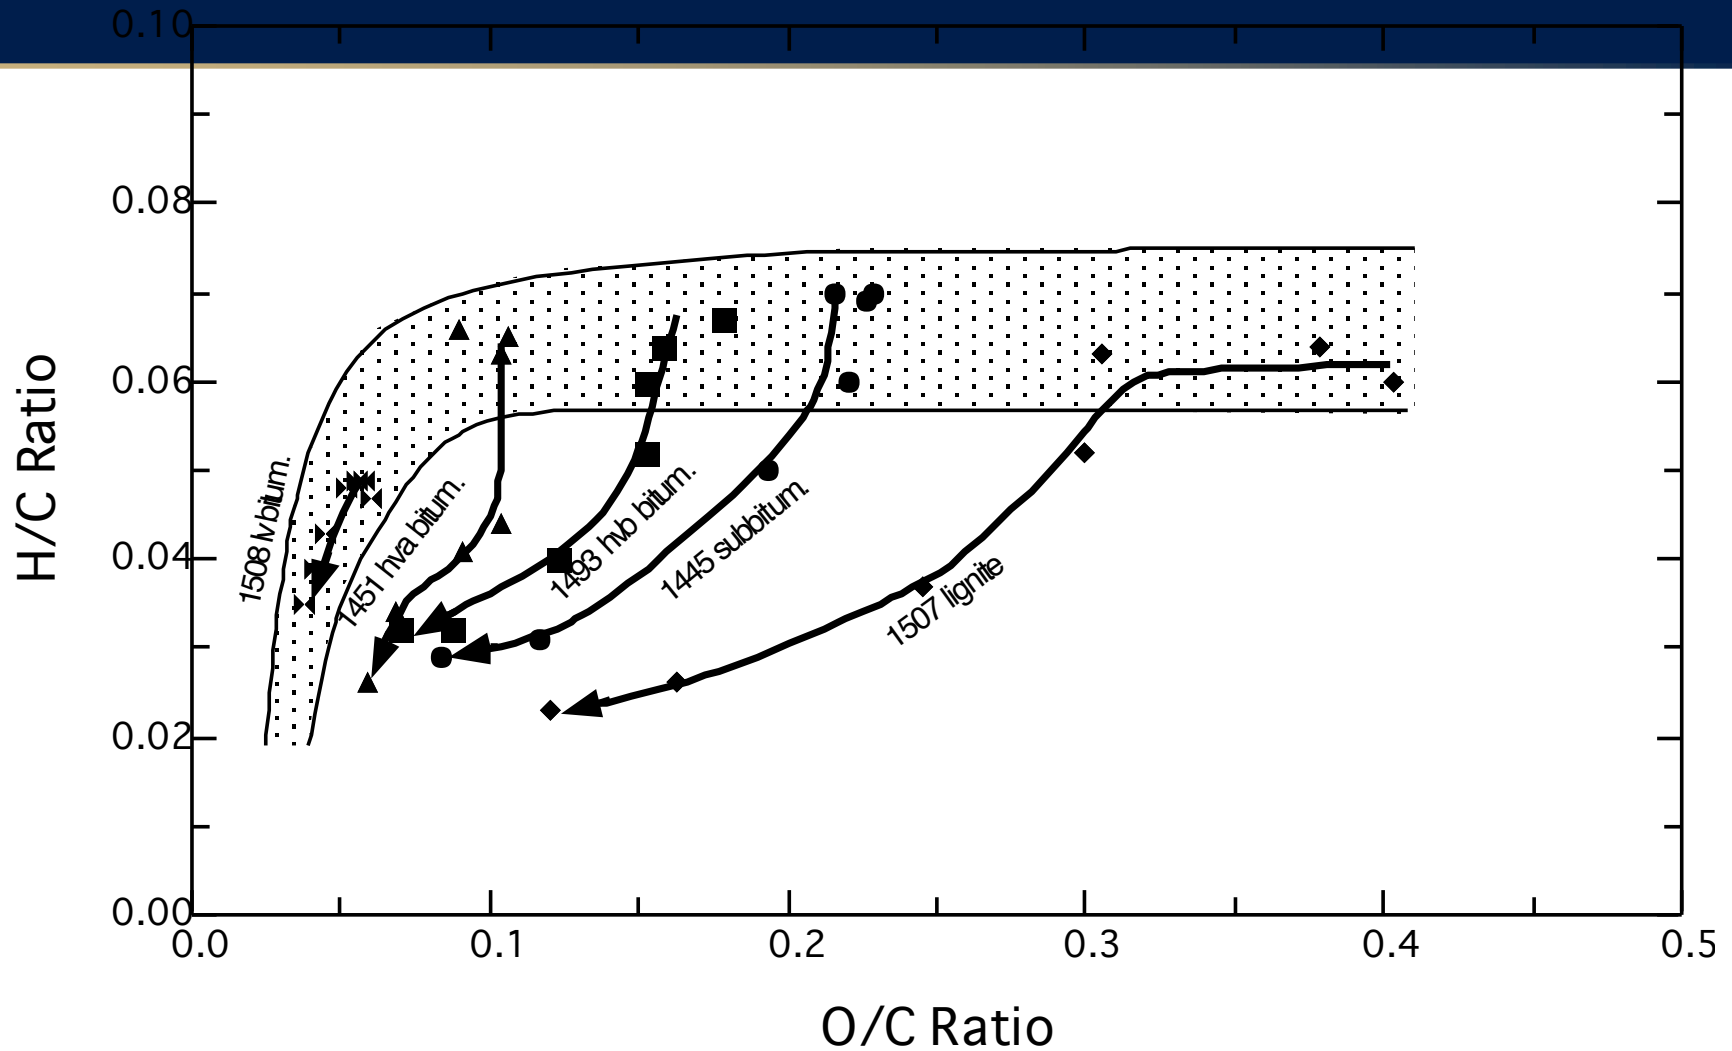

- FIMS of tars from the 8 Argonne Premium coal samples
  - Lignite to lv bituminous
- Similar profiles of the “dark” area where most of the mass occurs
- Average MW of tar is ~350 amu
- Tails reach 800 amu

Simmleit et al., in *Advances in Coal Spectroscopy*, Plenum, New York, pp. 295-339 (1992)

**Figure 28.** Integrated py-FI mass spectra (50–750°C) of Beulah–Zap (a,  $\bar{M}_n = 292$ ), Wyodak (b,  $\bar{M}_n = 338$ ), Illinois #6 (c,  $\bar{M}_n = 368$ ), Blind Canyon (d,  $\bar{M}_n = 336$ ), Lewiston–Stockton (e,  $\bar{M}_n = 327$ ), Pittsburgh (f,  $\bar{M}_n = 324$ ), Upper Fremont (g,  $\bar{M}_n = 368$ ), and Pocahontas #3 (h,  $\bar{M}_n = 359$ ). Heating rate 100 K/m (Simmleit *et al.*, 1992).

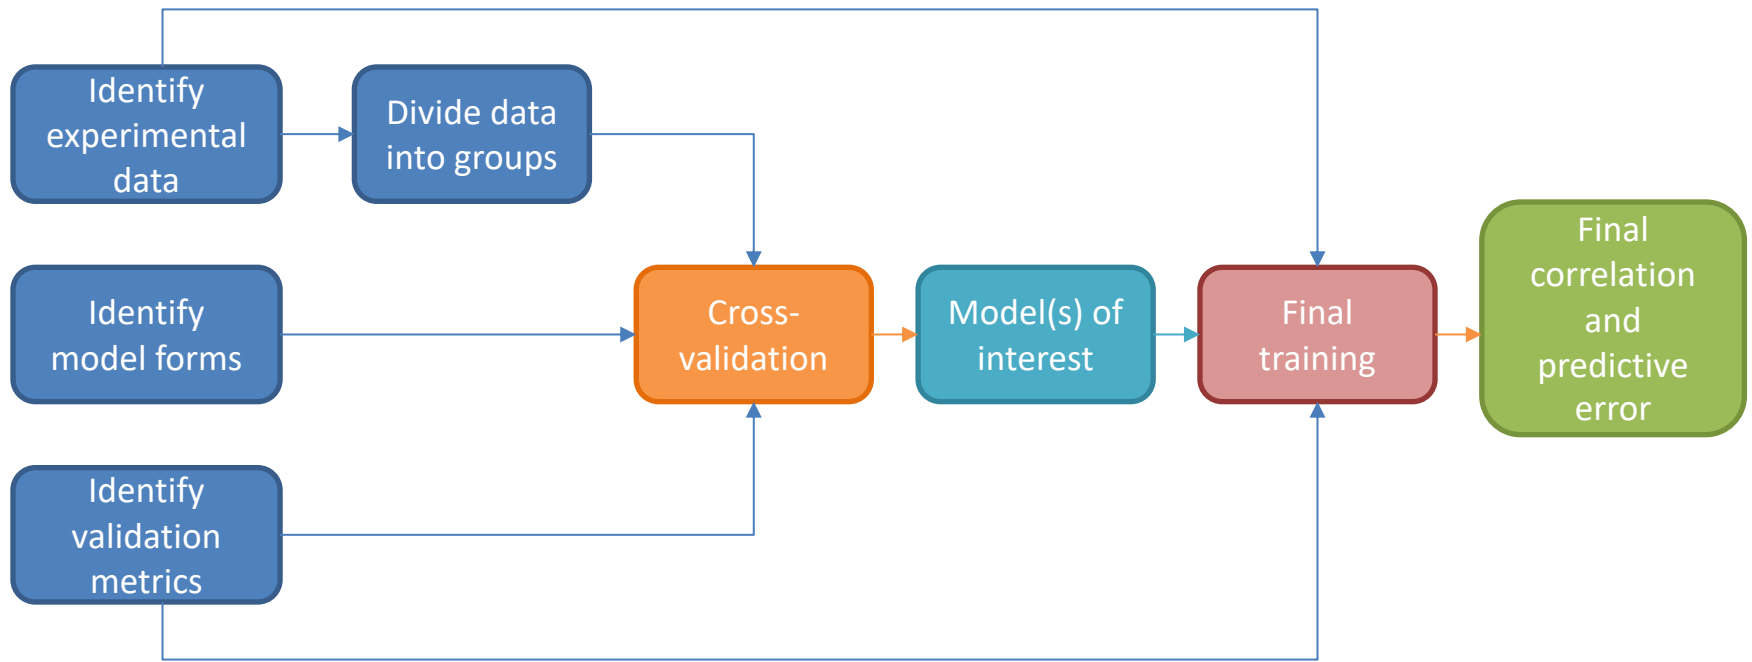

# Changes in Char during Pyrolysis

# Correlation of Elemental Composition of Coal Tars and Chars

- Gathered sets of composition data that included:
  - Maximum temperature
  - Heating rate
  - Residence time
  - Parent coal composition
    - Ultimate analysis (Elemental composition)
    - Proximate analysis (volatiles, moisture, ash)
- Correlated vs. combinations of the above parameters, plus:
  - Chemical structure parameters (from  $^{13}\text{C}$  NMR or NMR correlation)
- Total of 172 model forms attempted for correlation

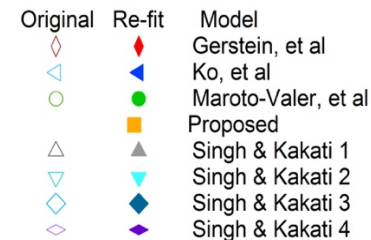

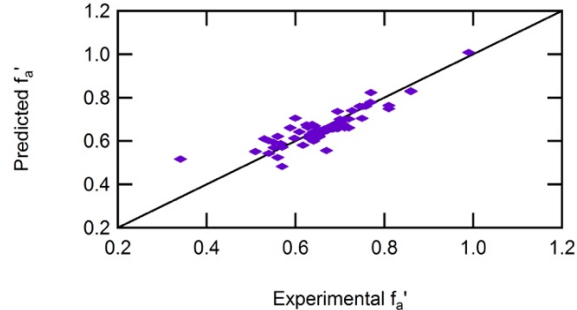

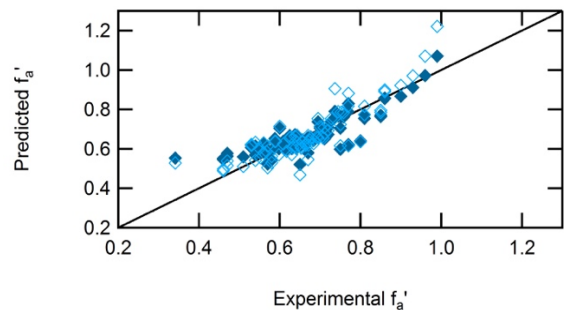

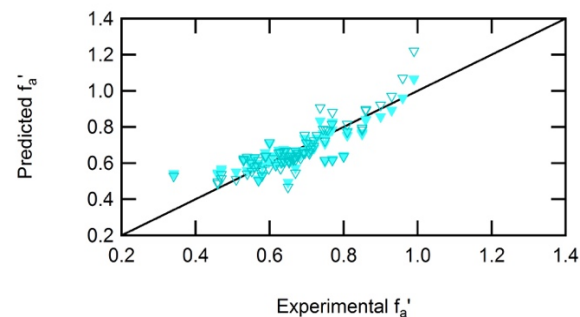

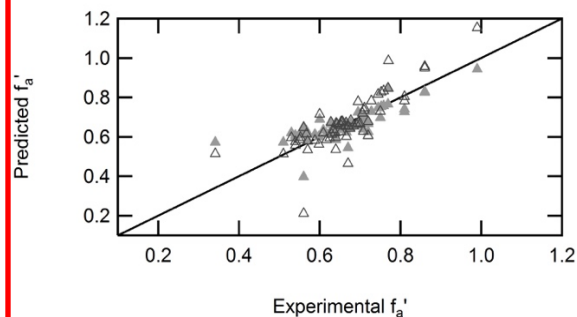

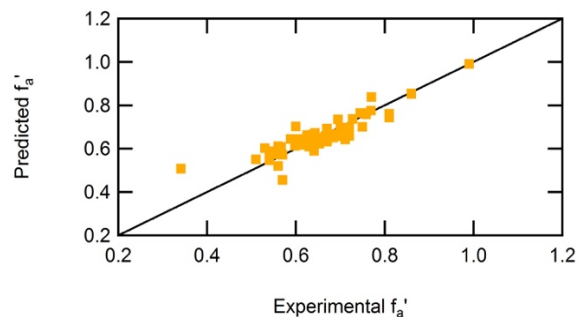

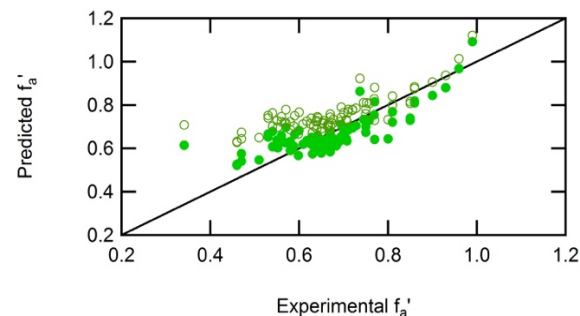

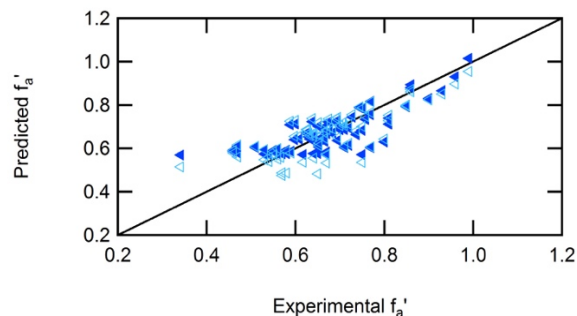

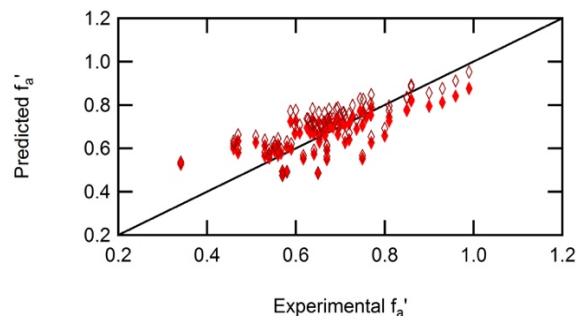

# Cross-Validation Process

## Cross validation:

1. Divide data into 10 separate groups
2. Use 9 of 10 groups to fit data
3. Use the unused group for independent evaluation
4. Repeat steps 2 & 3, rotating which is the independent group

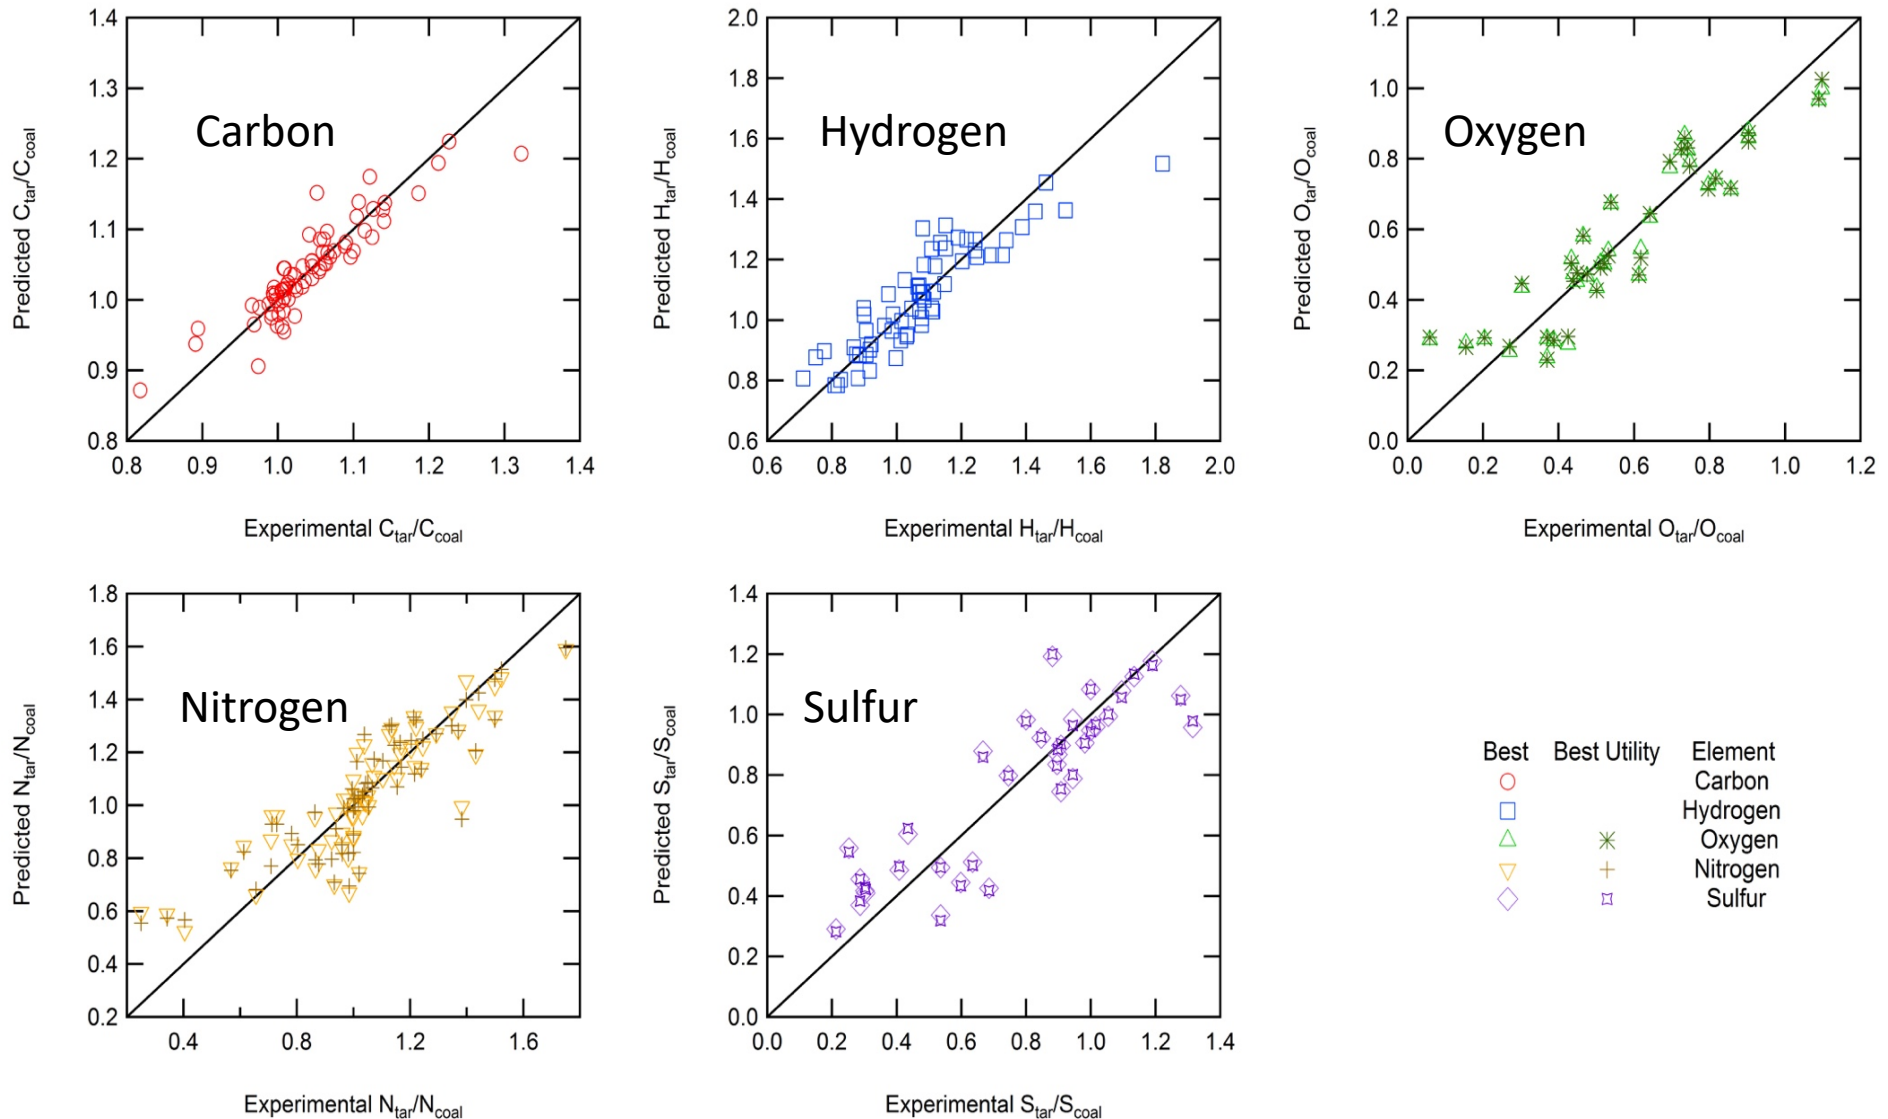

# Aromaticity Correlation

# Best Coal Aromaticity Correlation

$$f'_a = c_1 + c_2 C_{coal} + c_3 C_{coal}^2 + c_4 H_{coal} + c_5 H_{coal}^2 + c_6 O_{coal} + c_7 O_{coal}^2 + c_8 V_{ASTM} + c_9 V_{ASTM}^2$$

# Tar Correlations

# Tar Correlations

(C & H in tar)

$$\frac{C_{tar}}{C_{coal}} = c_1 + c_2 T_{gas,max} + \frac{1}{c_3 T_{gas,max}^3 + c_4 T_{gas,max}^4} + c_5 t_{res} + \frac{1}{c_6 t_{res}^2 + c_7 t_{res}^4} + \frac{1}{1 + c_8 V_{norm}^3} + c_9 C_{coal} + \frac{1}{c_{10} C_{coal}^2 + c_{11} C_{coal}^4}$$

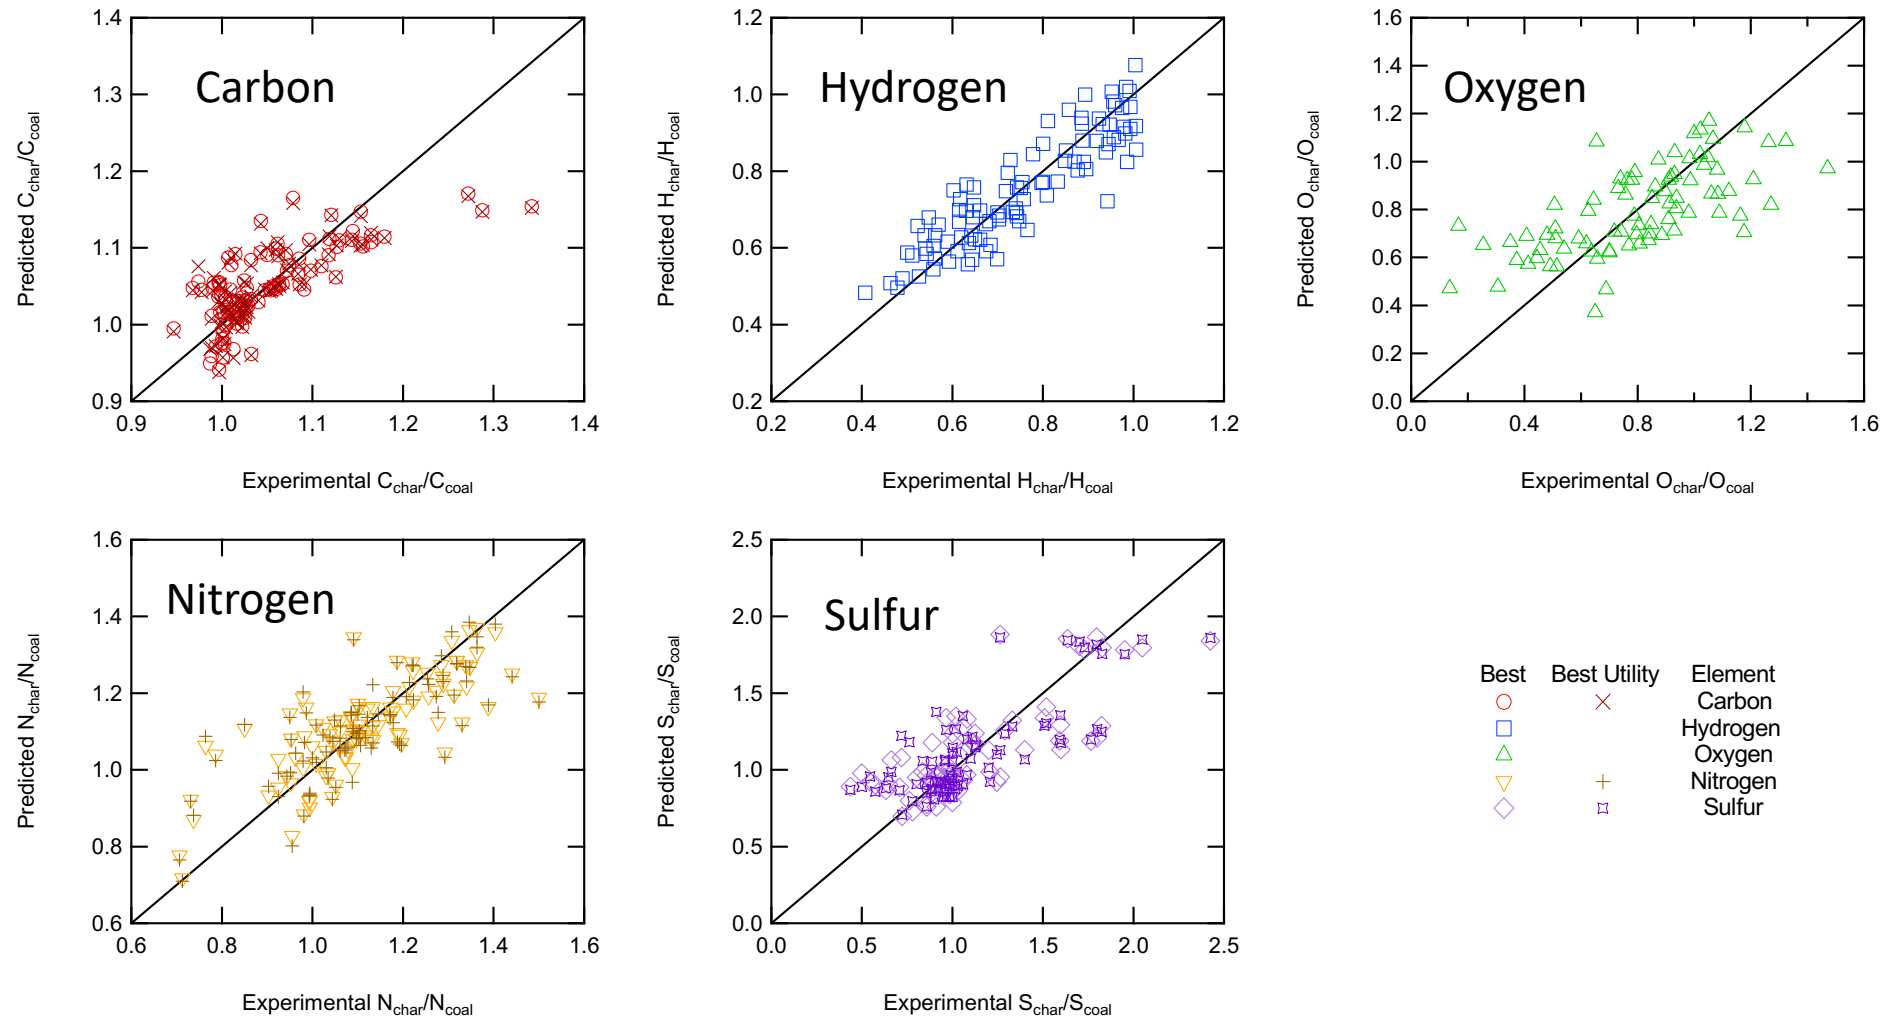

$$\frac{H_{tar}}{H_{coal}} = c_1 + c_2 T_{gas,max} + c_3 t_{res} + c_4 t_{res}^2 + c_5 t_{res}^3 + c_6 V_{norm} + c_7 V_{norm}^2 + c_8 V_{norm}^3 + c_9 M_{\delta,Genetti} + c_{10} M_{\delta,Genetti}^2$$

Where

$$V_{norm} = V_{meas}/V_{\infty}$$

$M_{\delta,Genetti}$  = MW of a side chain in the parent coal, from NMR correlation

# Correlation of Coal Char

# Char Correlations

(C & H in tar)

$$\frac{C_{char}}{C_{coal}} = c_1 + c_2 T_{gas,max} + c_3 T_{gas,max}^{\frac{1}{2}} + c_4 T_{gas,max}^{\frac{1}{4}} + c_5 t_{res} + c_6 t_{res}^{\frac{1}{2}} + c_7 t_{res}^{\frac{1}{3}} + c_8 t_{res}^{\frac{1}{4}} + c_9 \exp(V_{norm}) + c_{10} C_{coal} + c_{11} C_{coal}^{\frac{1}{2}}$$

$$\frac{H_{char}}{H_{coal}} = c_1 + c_2 T_{gas,max}^{c_3} + c_4 t_{res}^{c_5} + c_6 V_{norm}^{c_7} + c_8 H_{coal}^{c_9} + c_{10} V_{ASTM}^{c_{11}}$$

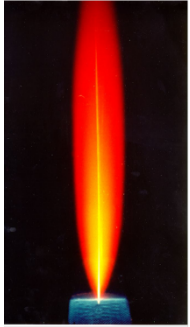

# Application to Simulations

1. Estimate heating rate and gas temperature conditions
2. Select coal type and get coal composition data
3. Use correlations to get elemental composition of tar & char
  - gas composition by difference
4. Estimate heat of formation for tar, char, & gas
5. Use with equilibrium code & assumed shape PDF method
  - Possible to have 3 coal gas mixture fractions?
  - Compatible with soot model?

# Outline

1. Volatiles Composition
- 2. Soot formation**
3. Char Oxidation

# Why Soot?

- Particles heavily impact radiative heat transfer
- Changes near-burner flame temperature and hence chemistry
- Health and environmental impacts

## Gaseous Fuels

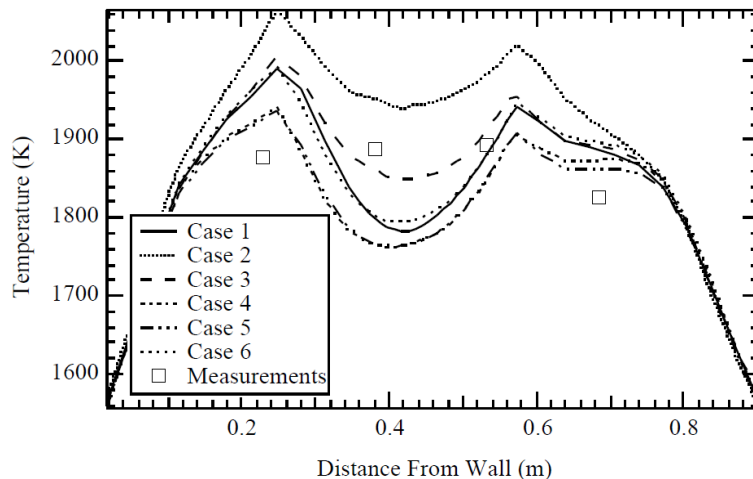

- Hydrocarbons form acetylene-like radicals
- Acetylene radicals form benzene, PAHs
- Soot precursors are PAHs

## Solid Fuels

- Coal gives off tar during primary pyrolysis
- Tar is primary soot precursor
- Only small influence of acetylene mechanism

# Previous Soot Model

(Brown & Fletcher, E&F 1998)

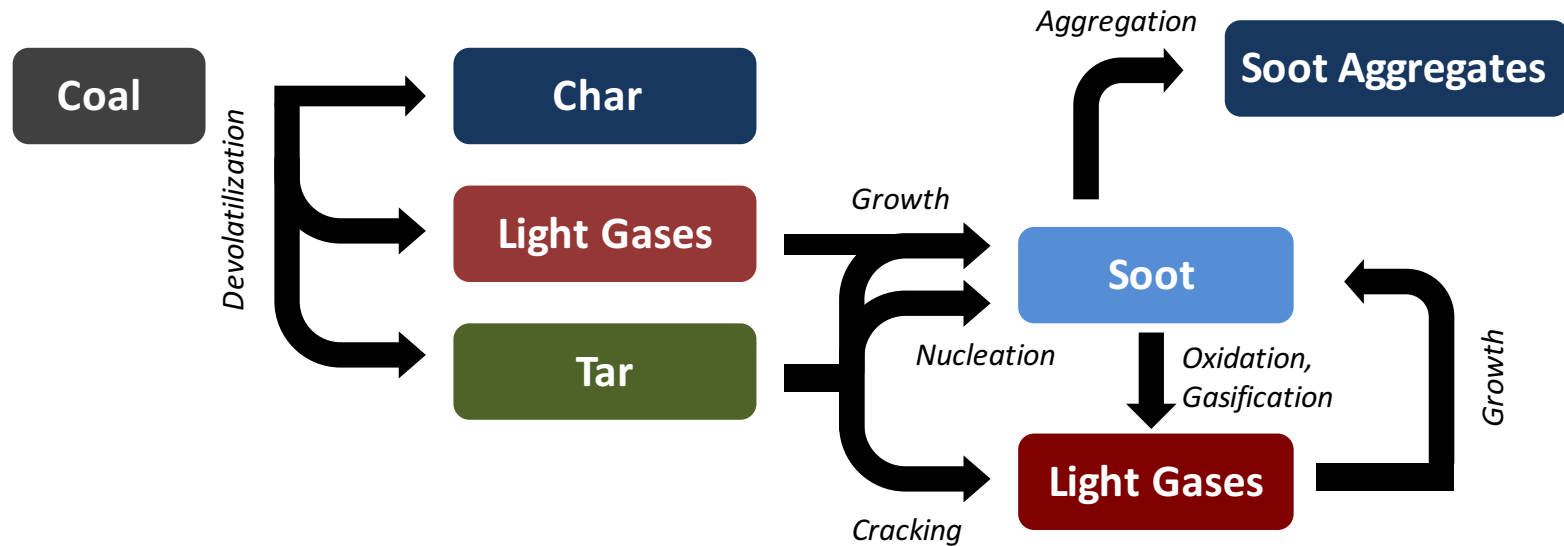

Predicted and measured gas temperatures in the FPTF at 144.8 cm above the inlet.  
(from Brown, 1997)

- CPD model to predict tar yield
- Empirical model for tar  $\rightarrow$  soot
- Soot growth and oxidation modeled
- Near burner flame temperature **decreased by 300 K** when soot was modeled

# Detailed soot model

(Josephson & Lignell, 2018)

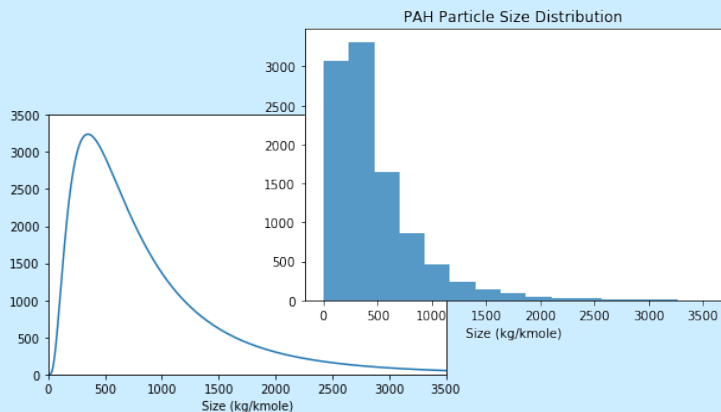

- **Key aspect: formation from tar**
- Tar acts as a nucleation source, and is “closer” to soot
- **Tar *formed*** from coal devolatilization
  - *Consumed* by oxidation, gasification, cracking, deposition, soot nucleation
- **Soot *formed*** from **tar** nucleation, deposition, **light gas** nucleation, growth
  - *Consumed* by oxidation, gasification, (coagulation, aggregation)

# Detailed soot model

## Precursors

- Sectional model
- Transport 9 sections (5 in Arches)
- Fixed bins
- CPD model output
  - tar yield
  - MW distribution
- Coagulation (FM) → soot

## Soot

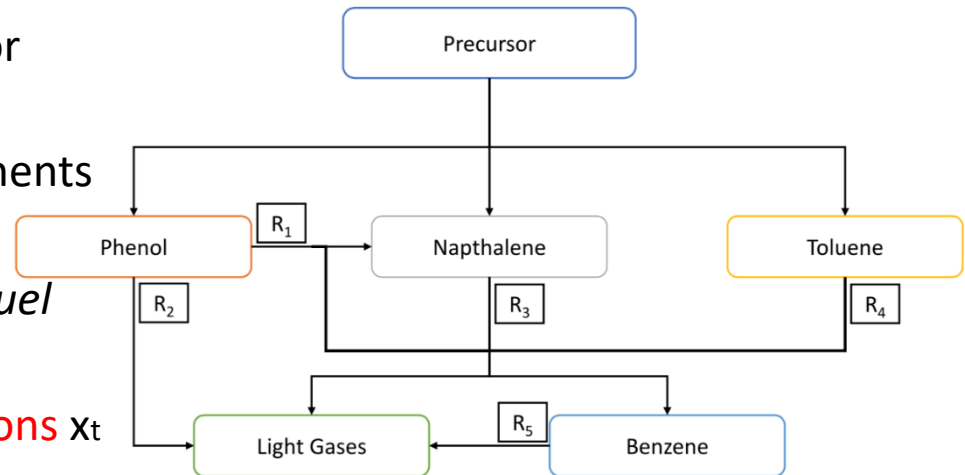

- MOMIC (**moment method**)
- Transport 6 moments (5 in Arches)
- Aggregation as in *Balthasar & Frenklach (2005)*
  - $M_{\langle d \rangle}$  transported
  - Defines a shape descriptor

$$\langle d \rangle = \frac{\log \mu_{\langle d \rangle}}{\log \mu_1} \quad \bullet \xrightarrow{2/3} 1 \bullet \bullet \bullet$$

- Tar nucleation
- Tar deposition (collisional growth)
- HACA growth ( $C_2H_2$ )
- $O_2+OH$  oxidation
- $CO_2+H_2O$  gasification

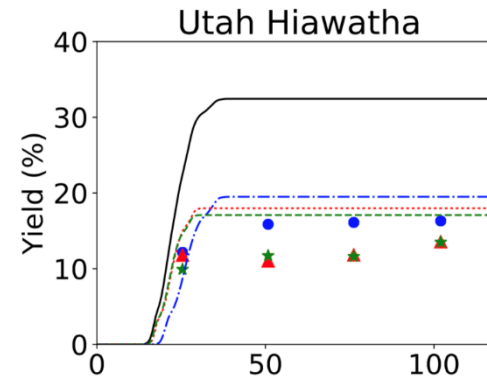

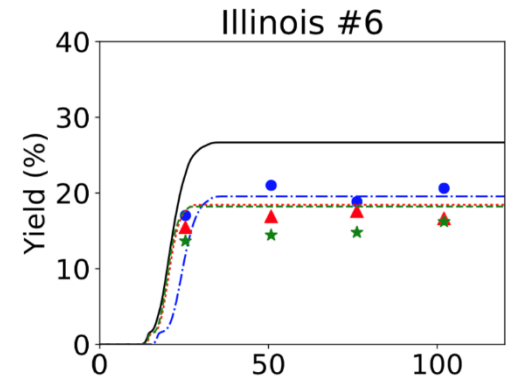

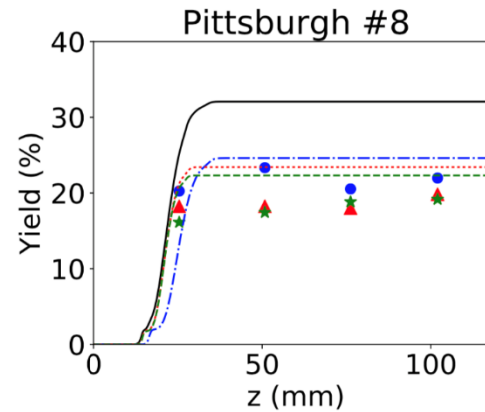

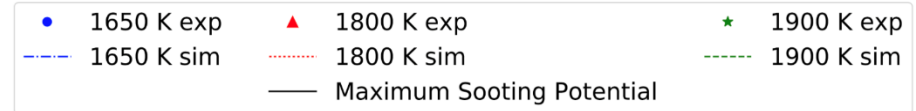

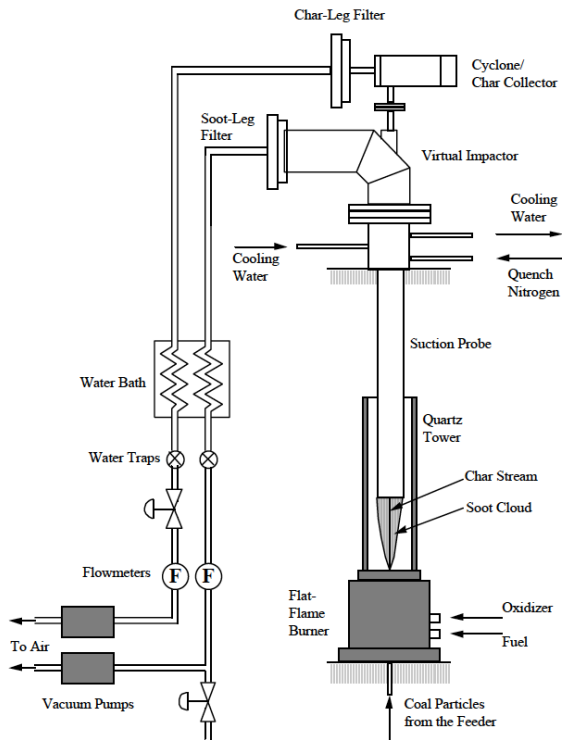

# Tar cracking model

- Tar cracking mechanism is important for accurate modeling.
- Tar molecules include aliphatic components and heteroatoms
- Model based on that by *Marias et al. Fuel Process. Technol. 149:139-152 (2016)*.
- Tars taken as consisting of 4 type fractions  $x_t$  as a surrogate:
  - Phenol, toluene, naphthalene, benzene
- Components react to others, or to gas phase
- Rates for each tar section are computed from  $x_t$ , reaction rates, and fraction of MW cracked to gas
- Type fractions  $x_t$  taken as constant, precomputed for each fuel type/system

| Reaction                                                                 | Rates                                                                                    |
|--------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| $C_6H_6O \rightarrow CO + 0.4C_{10}H_8 + 0.15C_6H_6 + 0.1CH_4 + 0.75H_2$ | $R_1 = k_1[C_6H_6O]$<br>$k_1 = 1.00E7 \exp\left(\frac{-1.0E5}{RT}\right)$                |
| $C_6H_6O + 3H_2O \rightarrow 2CO + CO_2 + 3CH_4$                         | $R_2 = k_2[C_6H_6O]$<br>$k_2 = 1.00E8 \exp\left(\frac{-1.0E5}{RT}\right)$                |
| $C_{10}H_8 + 4H_2O \rightarrow C_6H_6 + 4CO + 5H_2$                      | $R_3 = k_3[C_{10}H_8][H_2]^{0.4}$<br>$k_3 = 1.58E12 \exp\left(\frac{-3.24E5}{RT}\right)$ |
| $C_7H_8 + H_2 \rightarrow C_6H_6 + CH_4$                                 | $R_4 = k_4[C_7H_8][H_2]^{0.5}$<br>$k_4 = 1.04E12 \exp\left(\frac{-2.47E5}{RT}\right)$    |
| $C_6H_6 + 5H_2O \rightarrow 5CO + 6H_2 + CH_4$                           | $R_5 = k_5[C_6H_6]$<br>$k_5 = 4.40E8 \exp\left(\frac{-2.2E5}{RT}\right)$                 |

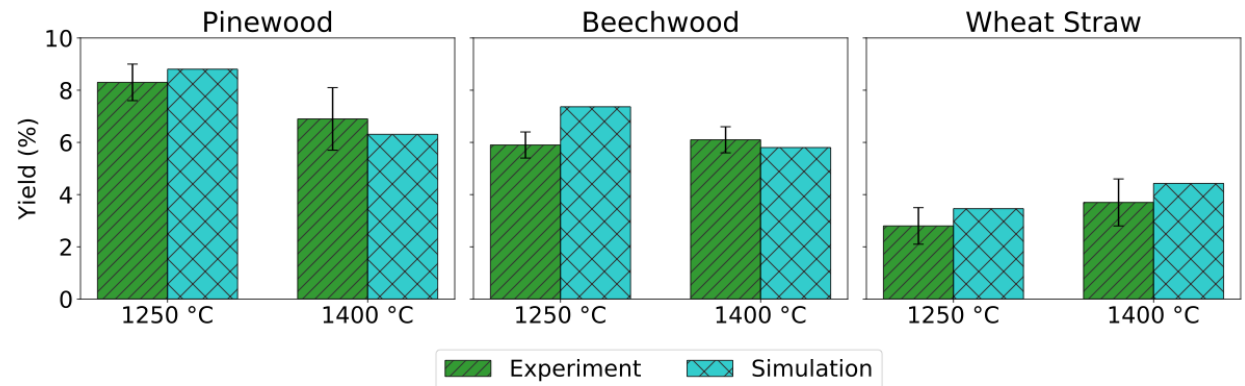

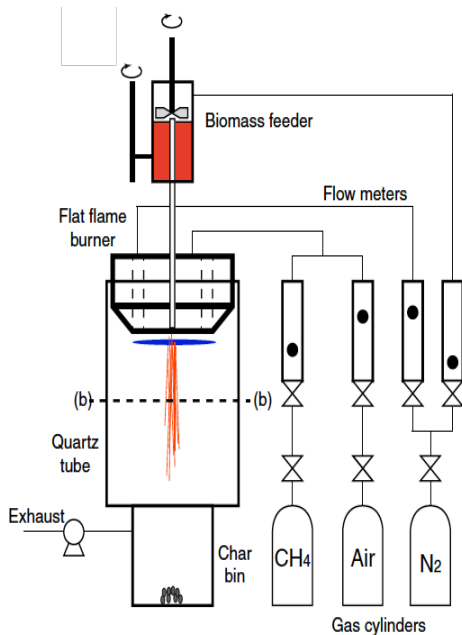

# Validation—Coal

- BYU laminar flat flame burner experiments
- *Ma et al. (1996, 1998)*
- CPD model predicts tar
- Soot model compared with Ma's data

# Validation—Biomass (soot yields)

- Trubetskaya et al., *Applied Energy*, 171, 2016
- Fast pyrolysis drop tube reactor
- Two temperatures: 1250, 1400 °C
- Precursors from CPD-bio

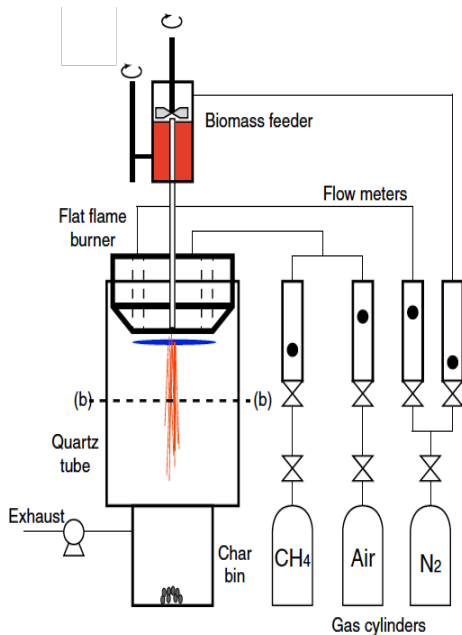

Good agreement with measured soot yield for biomass pyrolysis!  
True prediction – no tunable parameters!

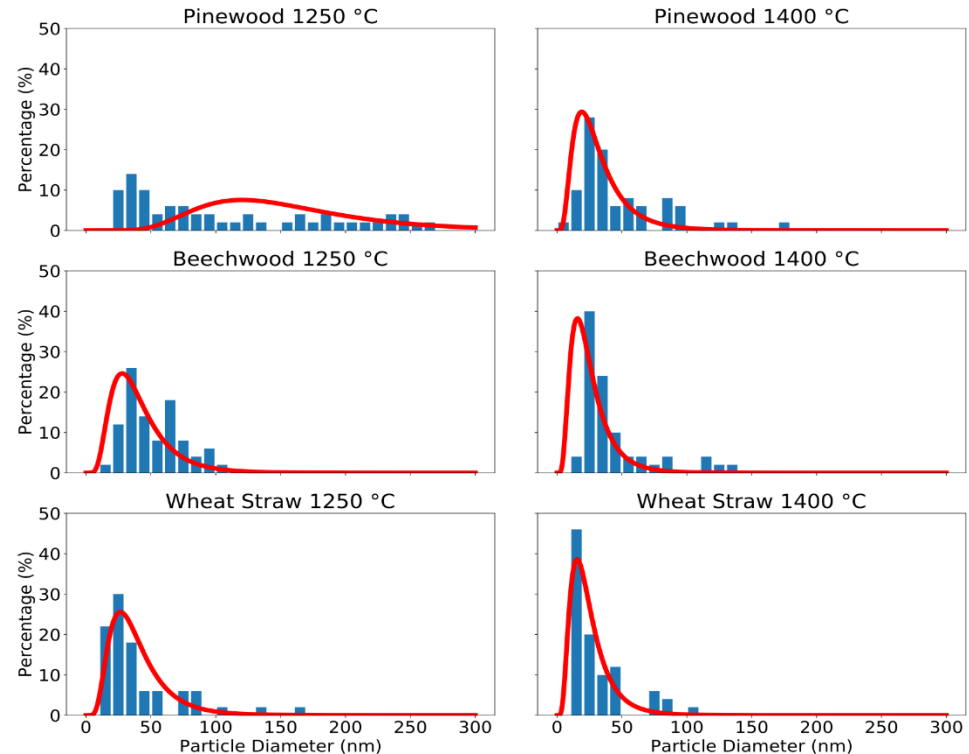

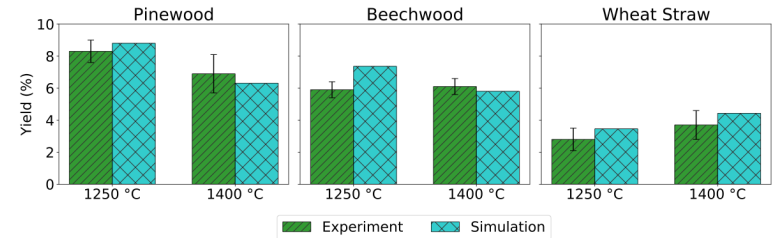

# Validation—Biomass

## (MW distributions)

- Trubetskaya et al., *Applied Energy*, 171, 2016
- Fast pyrolysis drop tube reactor
- Two temperatures: 1250, 1400 °C
- Precursors from CPD-bio

Trubetskaya et al., *Applied Energy*, 171, 2016

Reasonable agreement with soot size distribution!

# Reduced Soot Model

- Detailed model reduced for computational efficiency
  - 5-9 tar sections  $\rightarrow$  1 section
    - Transport  $N_t$  ( $\#/m^3$ )
  - 5-6 soot moments  $\rightarrow$  2 moments
    - Transport  $N_s, Y_s$
  - Assume spherical particles
    - No “d” moment:  $M_{<d>}$
  - Most chemistry is the same
- Correlate tar cracking type fractions  $x_t$
- Sooting potential model

# Sooting Potential Model

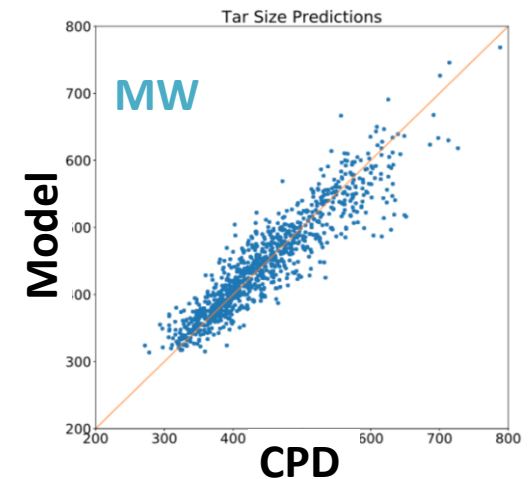

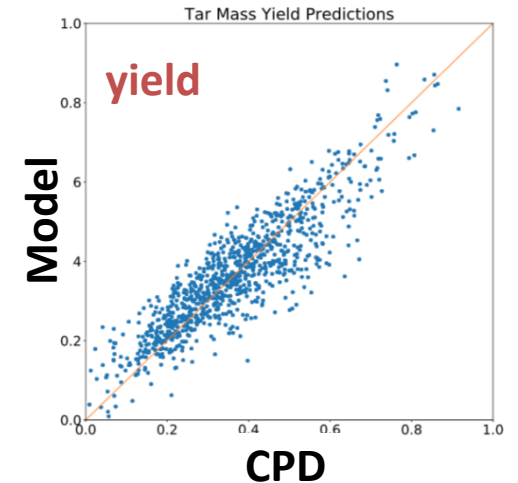

- CPD run many times varying input parameters
  - T:  $800 < T \text{ (K)} < 3000$
  - P:  $0.1 < P \text{ (atm)} < 100$ ,
  - O:C ratio:  $0.01 < O:C < 0.35$
  - H:C ratio:  $0.3 < H:C < 1.1$
  - Volatiles:  $2 < \%Vol < 80$
- Correlation: tar yield and tar MW

$$y_{tar} = \frac{-124.2 + 35.7P + 93.5O_C - 223.9O_C^2 + 284.8H_C - 107.3H_C^2 + 5.48V + 0.014V^2 - 58.2PC_H - 0.521PV - 5.32H_CV}{-303.8 + 52.4P + 1.55E3O_C - 2.46E3O_C^2 + 656.9H_C - 266.3H_C^2 + 15.9V + 0.025V^2 - 90.0PH_C - 462.5O_CH_C + 4.80O_CV - 17.8H_CV}$$

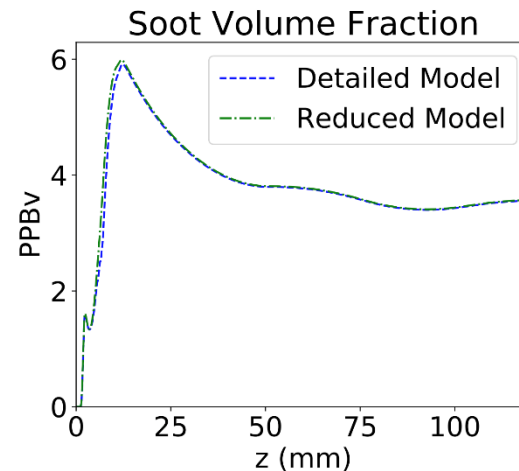

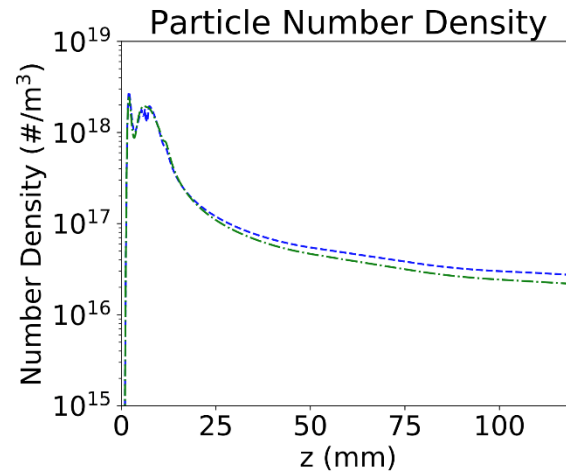

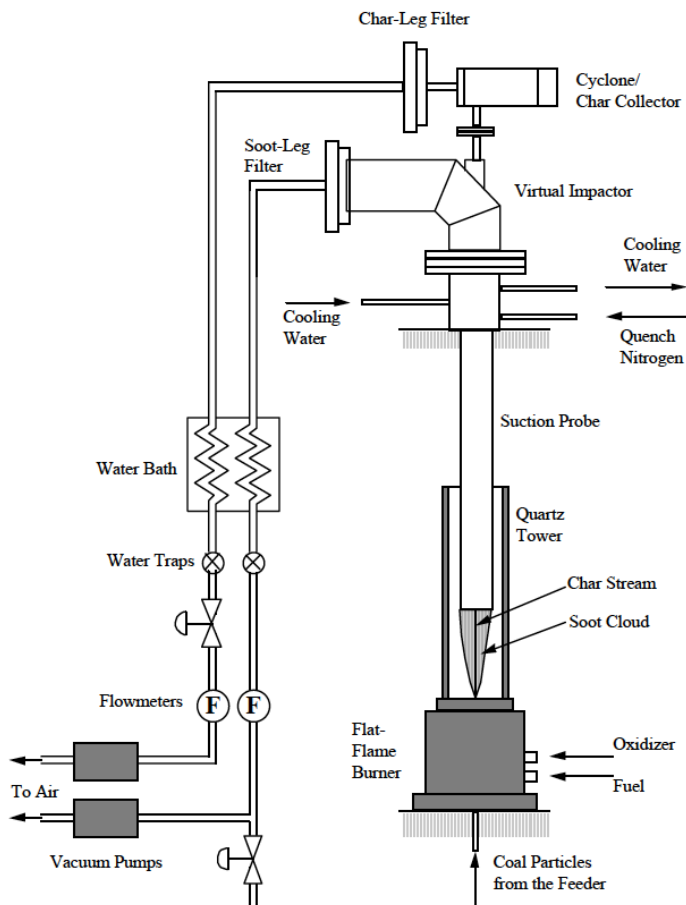

$$m_{tar} = \frac{3.12E5 + 16.4T_g + 4.34E5O_C - 8.48E5H_C + 6.38E5H_C^2 - 361.3V - 0.221T_gV - 6.39E5O_CH_C + 1.91E3H_CV}{753.6 + 0.042T_g + 83.9O_C - 1.77E3H_C + 1.20E3H_C^2 + 5.09E-3T_gP - 0.024T_gH_C - 5.27E-4T_gV + 0.513PV - 361.0O_CH_C + 3.83H_CV}$$

MW

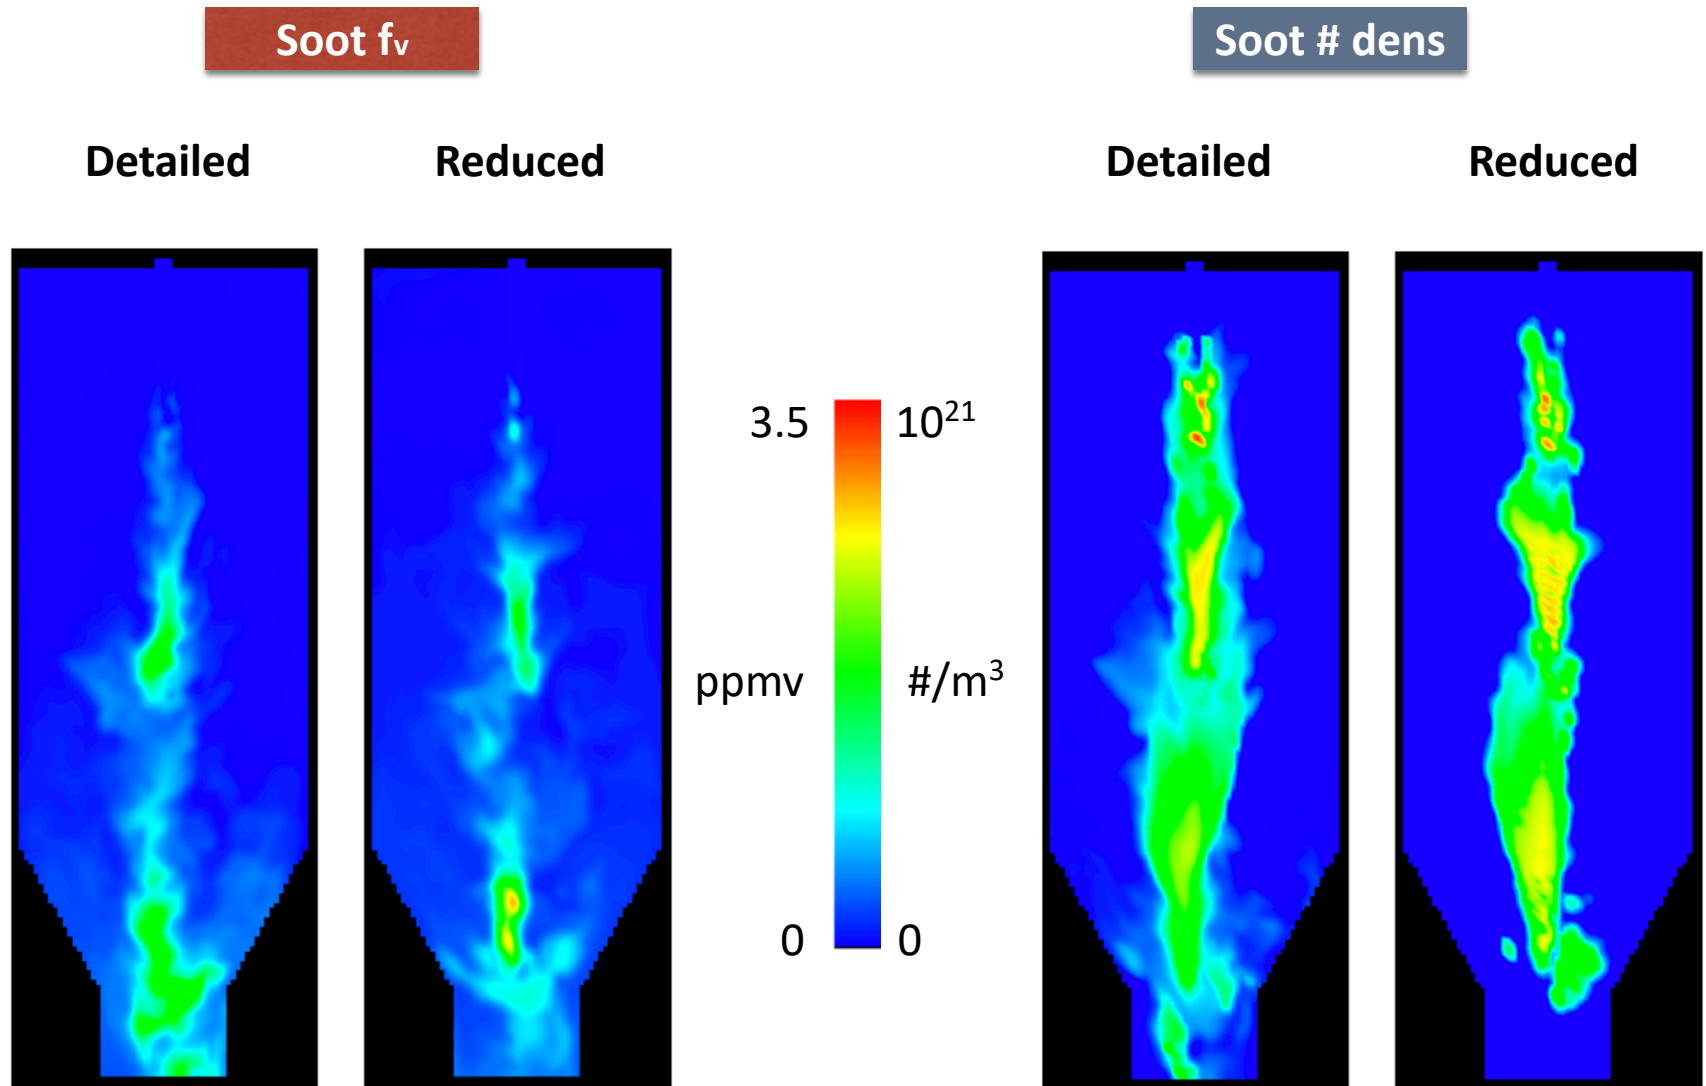

P is log(P)

# Validation—flat flame burner

# Arches simulation—OFC

# Outline

1. Volatiles Composition
2. Soot formation
3. Char Oxidation

# Wanted:

## Coal General Model of Char Oxidation

- Char properties are affected by many factors:
  - Parent coal properties
  - Size
  - Preparation conditions
    - Heating rate
    - Residence time
    - Pressure
    - Peak temperature
    - Oxidizing vs reducing conditions

# Comprehensive Char Oxidation/Gasification Models

- CBK (Hurt, et al.)
  - Intrinsic Char-O<sub>2</sub> kinetics
  - Thiele modulus for pore diffusion
  - Swelling model
  - Mode of burning and other parameters
  - Simple annealing model
- CBK-G (Niksa et al.)
  - Similar to CBK, except for gasification by CO<sub>2</sub>, H<sub>2</sub>O, & H<sub>2</sub>
- CCK (Holland & Fletcher)
  - Combined CBK and CBK-G
  - Improved annealing and swelling models

# Sensitivity Analysis on CCK for Oxy-fuel Conditions

- ▶ Determine which submodels/parameters are most important
  - ▶ Not including intrinsic rates
- ▶ Global analysis varying all parameters simultaneously testing for both linear and non-linear sensitivity
- ▶ 27 parameters, 4 burn-out quartiles, 4 coals, 3 gas conditions, 2 quantities of interest, and 2 types of sensitivity analysis  $\approx 5,000$  measures of sensitivity extracted from 120,000 computational experiments

| Parameter                              | Importance |
|----------------------------------------|------------|
| $E_A$ (annealing act. energy)          | 0.74       |
| $n_1$ (reaction order)                 | 0.51       |
| $d/d_0$ (swelling)                     | 0.27       |
| $\alpha$ (mode of burning)*            | 0.20       |
| $d_{\text{grain}}$ (ash grain size)    | 0.20       |
| $\sigma_{EA}$ (distribution of $E_A$ ) | 0.18       |
| $t_r$ (residence time)                 | 0.14       |

# Possible Solution: Annealing Model (CBK)

$$A_{ox} = f[\textit{precursor}, T_p(t)] = A_0 f_{an}$$

Annealing factor

$$\ln(A_0) = 10.96 - 0.07136 * C$$

$$\frac{dN_i}{dt} = -A_d \exp\left(-E_{d,i}/(RT_p)\right) N_i$$
$$f_{an} = \sum f_i = \sum N_i / N_{i,o}$$

Distribution of sites

# Annealing during Pyrolysis vs Post-pyrolysis

## During Pyrolysis

- Coal type
  - Chemical structure
  - Pyrolysis yields
- Heating rate
  - Pyrolysis yields
  - Swelling
  - Pore size
  - Ash distribution
- Peak temperature
  - Pyrolysis yields
  - Ash layer porosity

## Post-pyrolysis

- Mode of burning
  - Constant diameter vs constant density
- Residence time
  - Changes in aromatic structure
- Changes with extent of conversion
  - Pore sizes
  - Ash layer
  - Distribution of reactivity
    - Most reactive stuff burns first

# Annealing Model: Holland Extension

- ▶ The distributed activation energy is bimodal and irregular
- ▶ The distribution (not just the reaction rate) depends on
  - ▶ coal particle heating rate ( $HR$ ),
  - ▶ peak temperature ( $T_p$ ), and
  - ▶ chemical structure ( $p_0$ )
- ▶  $O_2$  char conversion may be impacted differently by annealing than  $CO_2$  and  $H_2O$  char conversion

$$\frac{df_i}{dt} = -A_d * \exp\left(\frac{-E_{A_{anneal},i}}{RT}\right) * f_i$$

$$PDF(E_{A_{anneal},i}) = \frac{1}{E_{A_{anneal},i} * \sigma} \exp\left(-\frac{1}{2} \left(\frac{\ln(E_{A_{anneal},i}/\mu)}{\sigma}\right)^2\right)$$

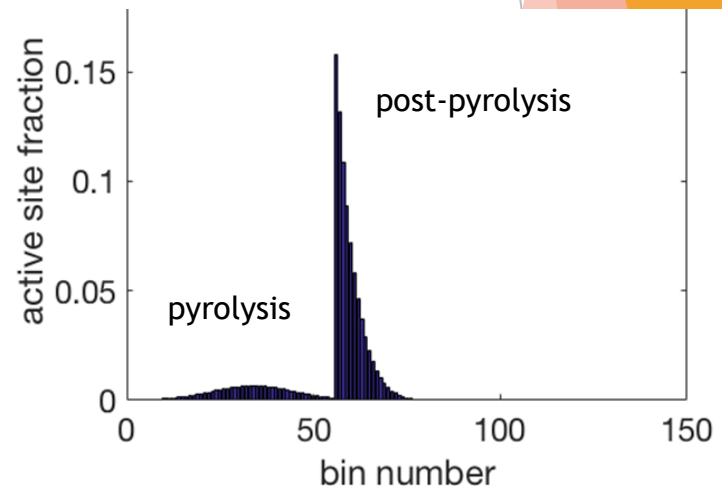

$$\mu = a * p_0 + b * T_{peak} + c$$

$$\sigma = \frac{d}{p_0}$$

$$A_d = \frac{p_0 * k_0}{\ln(10^4)} \quad \text{for } HR \geq 10^4$$

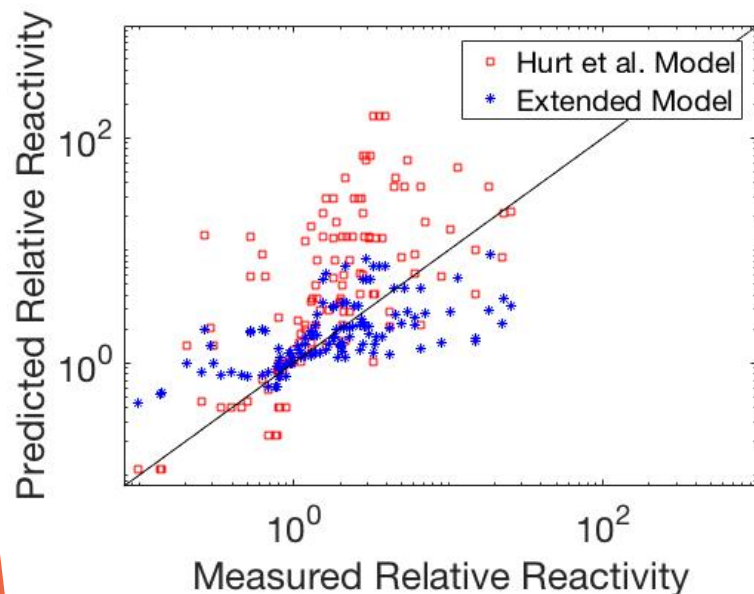

$$A_d = \frac{p_0 * k_0}{\ln(HR + 2.7)} \quad \text{for } HR < 10^4$$

| Parameter | Value                                 |
|-----------|---------------------------------------|
| $k_0$     | $1.398 * 10^{12} \text{ s}^{-1}$      |
| $a$       | $0.356 \text{ ln(kcal/mol)}$          |
| $b$       | $3.65 * 10^{-4} \text{ ln(kcal/mol)}$ |
| $c$       | $1.531 \text{ ln(kcal/mol)}$          |
| $d$       | $0.679 \text{ ln(kcal/mol)}$          |

Irregular distributed activation energy

# Annealing Model: Results by Holland & Fletcher

| Model Quantification                    | Hurt et al. Model    |         |         | Extended Model       |         |         |
|-----------------------------------------|----------------------|---------|---------|----------------------|---------|---------|
|                                         | Mean                 | Minimum | Maximum | Mean                 | Minimum | Maximum |
| Sum Squared Error                       | $1.45 \times 10^5$ * | N/A     | N/A     | $2.43 \times 10^3$ * | N/A     | N/A     |
| Error Factor: All Points                | <b>6.08</b>          | 1.00    | 51.97   | <b>2.24</b>          | 1.00    | 9.96    |
| Error Factor: Least Successful Quartile | 17.28                | 7.00    | 51.97   | 4.44                 | 2.30    | 9.96    |
| Error Factor: Most Successful quartile  | 1.13                 | 1.00    | 1.25    | 1.10                 | 1.00    | 1.20    |
| Error Factor: Central Quartiles         | 2.78                 | 1.25    | 6.50    | 1.63                 | 1.21    | 2.27    |

Error factor reduced from ~6 to ~2 using improved annealing model, including effects of:

- Coal type
- Heating rate
- Peak temperature

# Conclusions

- Hope for better chemistry in coal combustion/gasification simulations
  - Correlation for elemental composition of tar & char
  - Not CH<sub>4</sub> and Benzene
- Better treatment of tar leads to improved simulation of soot
  - Generalized soot model
  - Improved local temperature ( $T_g$ ) predictions
  - Improved  $T_g$  will lead to improved NO<sub>x</sub> calculations

# Conclusions (cont.)

- Hope for coal-general char conversion model
  - Reactivity affected by:
    - Char formation environment
    - Residence time during char conversion
    - Extent of char conversion
  - Annealing model used to treat pyrolysis & post-pyrolysis effects
  - Improved swelling model based on heating rate & coal type
  - Still work to do

# Acknowledgments

- This material is based upon work supported by the Department of Energy, National Nuclear Security Administration, under Award Number(s) DE-NA0002375

- Project work is a tri-university effort with support from the University of Utah, Brigham Young University, and University of California- Berkeley

- Project oversight and guidance is provided from three national labs: Lawrence Livermore, Sandia, and Los Alamos National Laboratories
